NoSQL!

NoSQL databases are currently a hot topic in some parts of computing, with over a hundred different NoSQL databases.

RDBMS Characteristics

- Data stored in columns and tables
- Relationships represented by data
- Data Manipulation Language
- Data Definition Language
- Transactions
- Abstraction from physical layer
- Applications specify what, not how
- Physical layer can change without modifying applications
 - Create indexes to support queries
 - In Memory databases

Transactions – ACID Properties

- Atomic All of the work in a transaction completes (commit) or none of it completes
 - a transaction to transfer funds from one account to another involves making a withdrawal operation from the first account and a deposit operation on the second. If the deposit operation failed, you don't want the withdrawal operation to happen either.
- Consistent A transaction transforms the database from one consistent state to another consistent state. Consistency is defined in terms of constraints.
 - a database tracking a checking account may only allow unique check numbers to exist for each transaction
- Isolated The results of any changes made during a transaction are not visible until the transaction has committed.
 - a teller looking up a balance must be isolated from a concurrent transaction involving a withdrawal from the same account. Only when the withdrawal transaction commits successfully and the teller looks at the balance again will the new balance be reported.
- Durable The results of a committed transaction survive failures
 - A system crash or any other failure must not be allowed to lose the results of a transaction or the contents of the database. Durability is often achieved through separate transaction logs that can "re-create" all transactions from some picked point in time (like a backup).

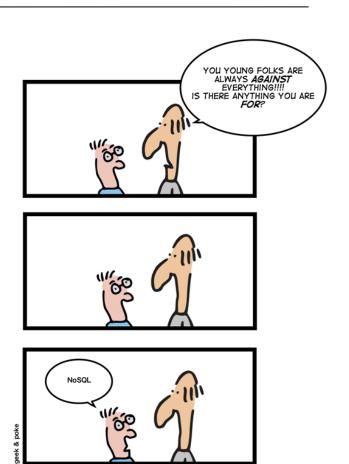

No SQL?

- NoSQL stands for:
 - No Relational
 - No RDBMS
 - Not Only SQL
- NoSQL is an umbrella term for all databases and data stores that don't follow the RDBMS principles
 - A class of products
 - A collection of several (related) concepts about data storage and manipulation
 - Often related to large data sets

NoSQL Definition

From www.nosql-database.org:

Next Generation Databases mostly addressing some of the points: being non-relational, distributed, opensource and horizontal scalable. The original intention has been modern web-scale databases. The movement began early 2009 and is growing rapidly. Often more characteristics apply as: schema-free, easy replication support, simple API, eventually consistent / BASE (not ACID), a huge data amount, and more.

Where does NoSQL come from?

- Non-relational DBMSs are not new
- But NoSQL represents a new incarnation
 - Due to massively scalable Internet applications
 - Based on distributed and parallel computing
- Development
 - Starts with Google
 - First research paper published in 2003
 - Continues also thanks to Lucene's developers/Apache (Hadoop) and Amazon (Dynamo)
 - Then a lot of products and interests came from Facebook, Netfix, Yahoo, eBay, Hulu, IBM, and many more

Dynamo and BigTable

- Three major papers were the seeds of the NoSQL movement
 - BigTable (Google)
 - Dynamo (Amazon)
 - Distributed key-value data store
 - Eventual consistency
 - CAP Theorem (discuss in a sec ..)

NoSQL and Big Data

- NoSQL comes from Internet, thus it is often related to the "big data" concept
- How much big are "big data"?
 - Over few terabytes Enough to start spanning multiple storage units
- Challenges
 - Efficiently storing and accessing large amounts of data is difficult, even more considering fault tolerance and backups
 - Manipulating large data sets involves running immensely parallel processes
 - Managing continuously *evolving schema* and metadata for *semi-structured* and *un-structured* data is difficult

How did we get here?

- Explosion of social media sites (Facebook, Twitter) with large data needs
- Rise of cloud-based solutions such as Amazon S3 (simple storage solution)
- Just as moving to dynamically-typed languages (Python, Ruby, Groovy), a shift to dynamically-typed data with frequent schema changes
- Open-source community

Why are RDBMS not suitable for Big Data

- The context is Internet
- RDBMSs assume that data are
 - Dense
 - Largely uniform (structured data)
- Data coming from Internet are
 - Massive and sparse
 - Semi-structured or unstructured
- With massive sparse data sets, the typical storage mechanisms and access methods get stretched

NoSQL Distinguishing Characteristics

- Large data volumes
 - Google's "big data"
- Scalable replication and distribution
 - Potentially thousands of machines
 - Potentially distributed around the world
- Queries need to return answers quickly
- Mostly query, few updates

- Asynchronous Inserts & Updates
- Schema-less
- ACID transaction properties are not needed – BASE
- CAP Theorem
- Open source development

NoSQL Database Types

Discussing NoSQL databases is complicated because there are a variety of types:

Sorted ordered Column Store

•Optimized for queries over large datasets, and store columns of data together, instead of rows

Document databases:

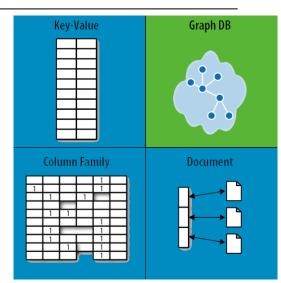

•pair each key with a complex data structure known as a document.

•Key-Value Store:

•are the simplest NoSQL databases. Every single item in the database is stored as an attribute name (or 'key'), together with its value.

•Graph Databases:

•are used to store information about networks of data, such as social connections.

Document Databases (Document Store)

Documents

- Loosely structured sets of key/value pairs in documents, e.g., XML, JSON, BSON
- Encapsulate and encode data in some standard formats or encodings
- Are addressed in the database via a unique key
- Documents are treated as a whole, avoiding splitting a document into its constituent name/value pairs
- Allow documents retrieving by keys or contents
- Notable for:
 - MongoDB (used in FourSquare, Github, and more)
 - CouchDB (used in Apple, BBC, Canonical, Cern, and more)

Document Databases (Document Store)

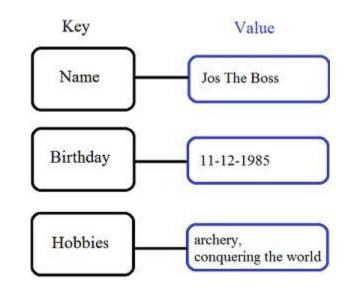

- The central concept is the notion of a "document" which corresponds to a row in RDBMS.
- A document comes in some standard formats like JSON (BSON).
- Documents are addressed in the database via a unique *key* that represents that document.
- The database offers an API or query language that retrieves documents based on their contents.
- Documents are schema free, i.e., different documents can have structures and schema that differ from one another. (An RDBMS requires that each row contain the same columns.)

Document Databases, JSON

```

    type: "Article",
    author: "Derick Rethans",
    title: "Introduction to Document Databases with MongoDB",
    date: ISODate("2013-04-24T16:26:31.911Z"),
    body: "This arti..."
},
    _id: ObjectId("51156a1e056d6f966f268f82"),
    type: "Book",
    author: "Derick Rethans",
    title: "php|architect's Guide to Date and Time Programming with PHP",
    isbn: "978-0-9738621-5-7"
```

Key/Value stores

- Store data in a schema-less way
- Store data as maps
 - HashMaps or associative arrays
 - Provide a very efficient average running time algorithm for accessing data
- Notable for:
 - Couchbase (Zynga, Vimeo, NAVTEQ, ...)
 - Redis (Craiglist, Instagram, StackOverfow, flickr, ...)
 - Amazon Dynamo (Amazon, Elsevier, IMDb, ...)
 - Apache Cassandra (Facebook, Digg, Reddit, Twitter,...)
 - Voldemort (LinkedIn, eBay, ...)
 - Riak (Github, Comcast, Mochi, ...)

Sorted Ordered Column-Oriented Stores

Data are stored in a column-oriented way

- Data efficiently stored
- Avoids consuming space for storing nulls
- Columns are grouped in column-families
- Data isn't stored as a single table but is stored by column families
- Unit of data is a set of key/value pairs
 - Identified by "row-key"
 - Ordered and sorted based on row-key

• Notable for:

- Google's Bigtable (used in all Google's services)
- HBase (Facebook, StumbleUpon, Hulu, Yahoo!, ...)

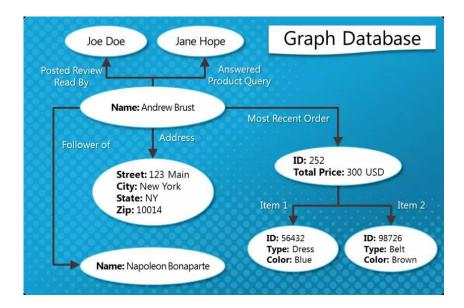

Sales

Graph Databases

- Graph-oriented
- Everything is stored as an edge, a node or an attribute.
- Each node and edge can have any number of attributes.
- Both the nodes and edges can be labelled.
- Labels can be used to narrow searches.

Dealing with Big Data and Scalability

- Issues with scaling up when the dataset is just too big
- RDBMS were not designed to be distributed
- Traditional DBMSs are best designed to run well on a "single" machine
 - Larger volumes of data/operations requires to upgrade the server with faster CPUs or more memory known as 'scaling up' or 'Vertical scaling'
- NoSQL solutions are designed to run on clusters or multinode database solutions
 - Larger volumes of data/operations requires to add more machines to the cluster, Known as 'scaling out' or 'horizontal scaling'
 - Different approaches include:
 - Master-slave
 - Sharding (partitioning)

Scaling RDBMS

Master-Slave

- All writes are written to the master. All reads performed against the replicated slave databases
- Critical reads may be incorrect as writes may not have been propagated down
- Large data sets can pose problems as master needs to duplicate data to

Sharding

- Any DB distributed across multiple machines needs to know in what machine a piece of data is stored or must be stored
- A sharding system makes this decision for each row, using its key

NoSQL, No ACID

- RDBMSs are based on ACID (Atomicity, Consistency, Isolation, and Durability) properties
- NoSQL
 - Does not give importance to ACID properties
 - In some cases completely ignores them
- In distributed parallel systems it is difficult/impossible to ensure ACID properties
 - Long-running transactions don't work because keeping resources blocked for a long time is not practical

BASE Transactions

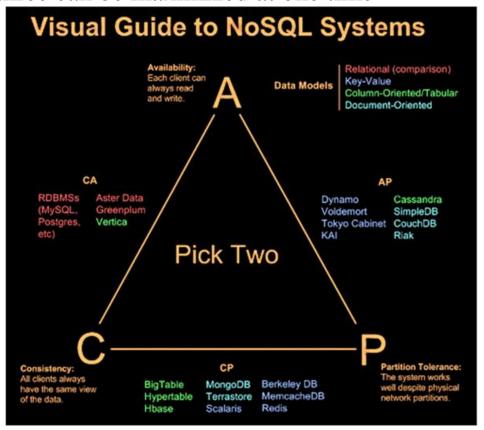

- Acronym contrived to be the opposite of ACID
 - Basically Available,
 - Soft state,
 - Eventually Consistent
- Characteristics
 - Weak consistency stale data OK
 - Availability first
 - Best effort
 - Approximate answers OK
 - Aggressive (optimistic)
 - Simpler and faster

CAP Theorem

A congruent and logical way for assessing the problems involved in assuring ACID-like guarantees in distributed systems is provided by the CAP theorem

At most two of the following three can be maximized at one time

- Consistency
 - Each client has the same view of the data
- Availability
 - · Each client can always read and write
- Partition tolerance
 - System works well across distributed physical networks

CAP Theorem: Two out of Three

- CAP theorem At most two properties on three can be addressed
- The choices could be as follows:
- 1. Availability is compromised but consistency and partition tolerance are preferred over it
- 2. The system has little or no partition tolerance. Consistency and availability are preferred
- 3. Consistency is compromised but systems are always available and can work when parts of it are partitioned

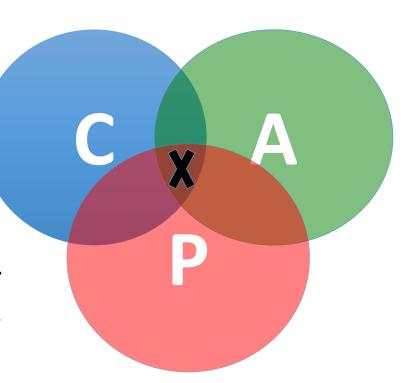

Consistency or Availability

• Consistency and Availability is not "binary" decision

• AP systems relax consistency in favor of availability – but are not inconsistent

• CP systems sacrifice availability for consistency- but are not unavailable

• This suggests both AP and CP systems can offer a degree of consistency, and availability, as well as partition tolerance

Performance

- There is no perfect NoSQL database
- Every database has its advantages and disadvantages
 - Depending on the type of tasks (and preferences) to accomplish
- NoSQL is a set of concepts, ideas, technologies, and software dealing with
 - Big data
 - Sparse un/semi-structured data
 - High horizontal scalability
 - Massive parallel processing
- Different applications, goals, targets, approaches need different NoSQL solutions

Where would I use it?

- Where would I use a NoSQL database?
- Do you have somewhere a large set of uncontrolled, unstructured, data that you are trying to fit into a RDBMS?
 - Log Analysis
 - Social Networking Feeds (many firms hooked in through Facebook or Twitter)
 - External feeds from partners
 - Data that is not easily analyzed in a RDBMS such as time-based data
 - Large data feeds that need to be massaged before entry into an RDBMS

Don't forget about the DBA

- It does not matter if the data is deployed on a NoSQL platform instead of an RDBMS.
- Still need to address:
 - Backups & recovery
 - Capacity planning
 - Performance monitoring
 - Data integration
 - Tuning & optimization
- What happens when things don't work as expected and nodes are out of sync or you have a data corruption occurring at 2am?
- Who you gonna call?
 - DBA and SysAdmin need to be on board

The Perfect Storm

- Large datasets, acceptance of alternatives, and dynamicallytyped data has come together in a perfect storm
- Not a backlash/rebellion against RDBMS
- SQL is a rich query language that cannot be rivaled by the current list of NoSQL offerings
 - So you have reached a point where a read-only cache and write-based RDBMS isn't delivering the throughput necessary to support a particular application.
 - You need to examine alternatives and what alternatives are out there.
 - The NoSQL databases are a pragmatic response to growing scale of databases and the falling prices of commodity hardware.

Summary

- Most likely, 10 years from now, the majority of data is still stored in RDBMS.
- Leading users of NoSQL datastores are social networking sites such as Twitter, Facebook, LinkedIn, and Digg.
- Not every problem is a nail and not every solution is a hammer.
- NoSQL has taken a field that was "dead" (database development) and suddenly brought it back to life.
